Fusarium wilt of pepper is caused by two species of fungi, *Fusarium oxysporum* and *Fusarium solani* f. sp. *piperi*, which are obligate hemibiotrophs. Pathogenicity of each species is determined by different physiological races of either the biotrophic or necrotrophic form. In nature, the hemibiotrophs colonize the host plant and then switch to the necrotrophic stage to kill the plant. Some changes in the physiology and morphology of *Fusarium* are known to occur in the wild host species. In pepper, the initial morphological changes occur in the necrotrophic stage, followed by the necrotrophic phase in the biotrophic stage. In nature, pepper is infected with a race of the hemibiotroph that colonizes the stem and roots, causing necrosis at the site of infection. When this pathogen switches to the necrotrophic phase of pathogenesis it produces toxins that kill the host. In the laboratory, pepper cultivars of the cv. Mombasa were found to be infected by *Fusarium oxysporum* f. sp. *piperi* and *F. solani* f. sp. *piperi* (San Pablo. R. M., et al. *Phytopathology* (1955), 35: 69–76, San Pablo. R. M., et al. *Phytopathology* (1956), 36: 433–438). San Pablo et al. demonstrated that *F. solani* f. sp. *piperi* was in the necrotrophic phase, and that this species killed the host plant. In the foregoing paper, San Pablo et al. reported that “there is no evidence of continuous growth of the fungus on the plant material, which indicates a change in the pathogen from a
